CM SAF data for heat mapping in Europe

Ana Casanueva **Sven Kotlarski** Anke Duguay-Tetzlaff

sven.kotlarski@meteoswiss.ch

The HEAT-SHIELD project

- EU Horizon 2020
- 01/2016 - 12/2020
- 20 partners
- www.heat-shield.eu

Main Objective:

Reduction of heat stress and heat impacts on the European work force

Improved heat forecasts, heat projections, heat warnings and adaptation measures

MeteoSwiss

- 21st Century heat exposure projections (European scale) 
 - Prototype of an **early warning system for heat exposure for the upcoming 4 weeks** (European scale)
- > «**Climate Services**» products

A worker's heat exposure

Wet Bulb Globe Temperature (WGBT)

- Most widely used heat stress index for working people
- Derivable from **standard meteorological variables**
- Can be interpreted for different **physiological settings, clothings** and **working environments**

Heat stress index

Full implementation («WGBT in the sun») considers

Temperature

Humidity

Wind

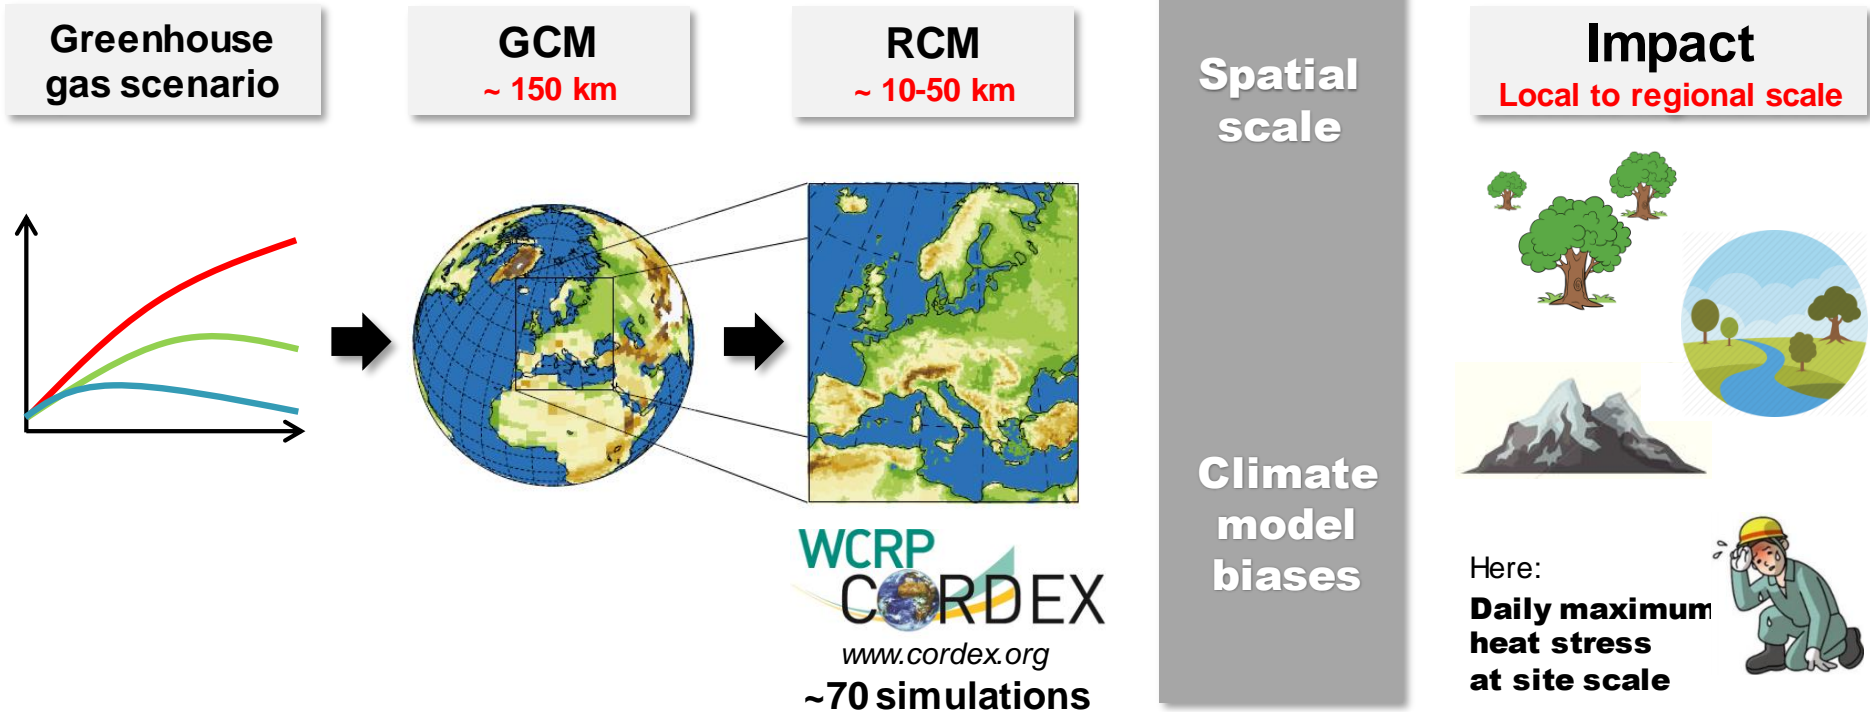

Solar radiation

Climate projections:

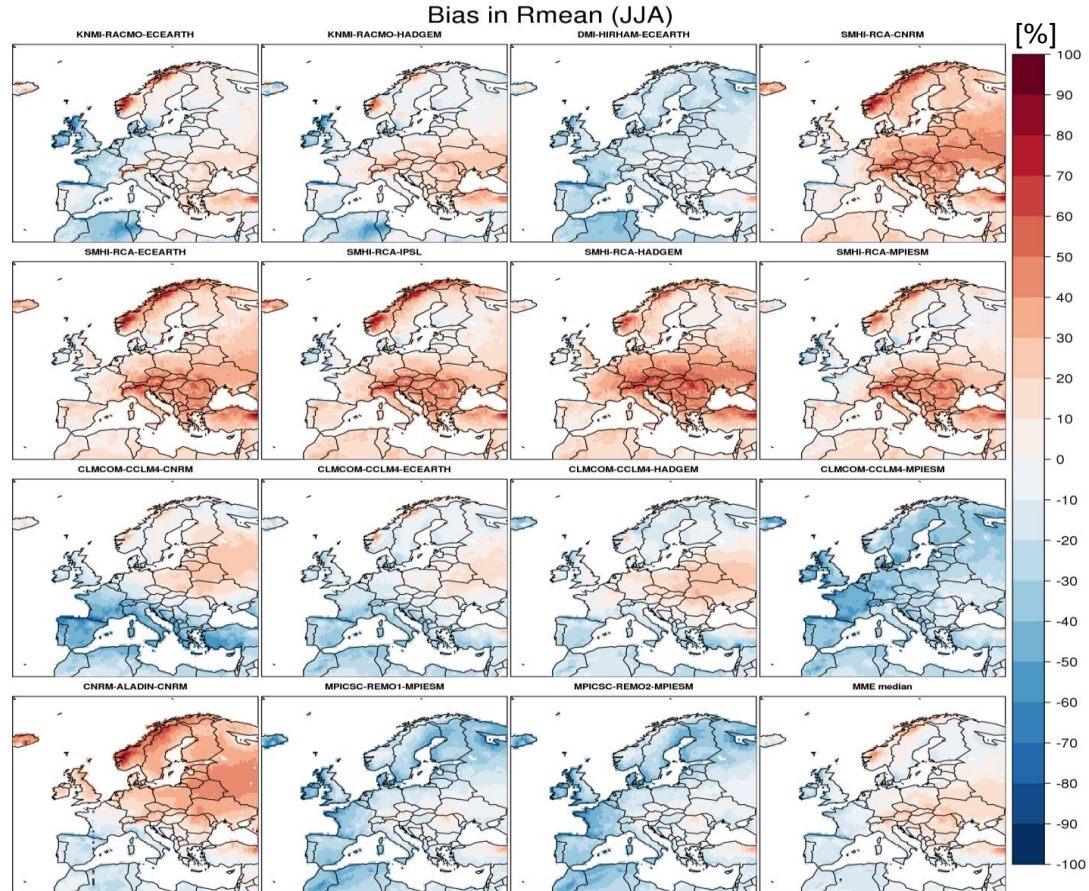

The standard processing chain

Climate model biases in JJA global radiation

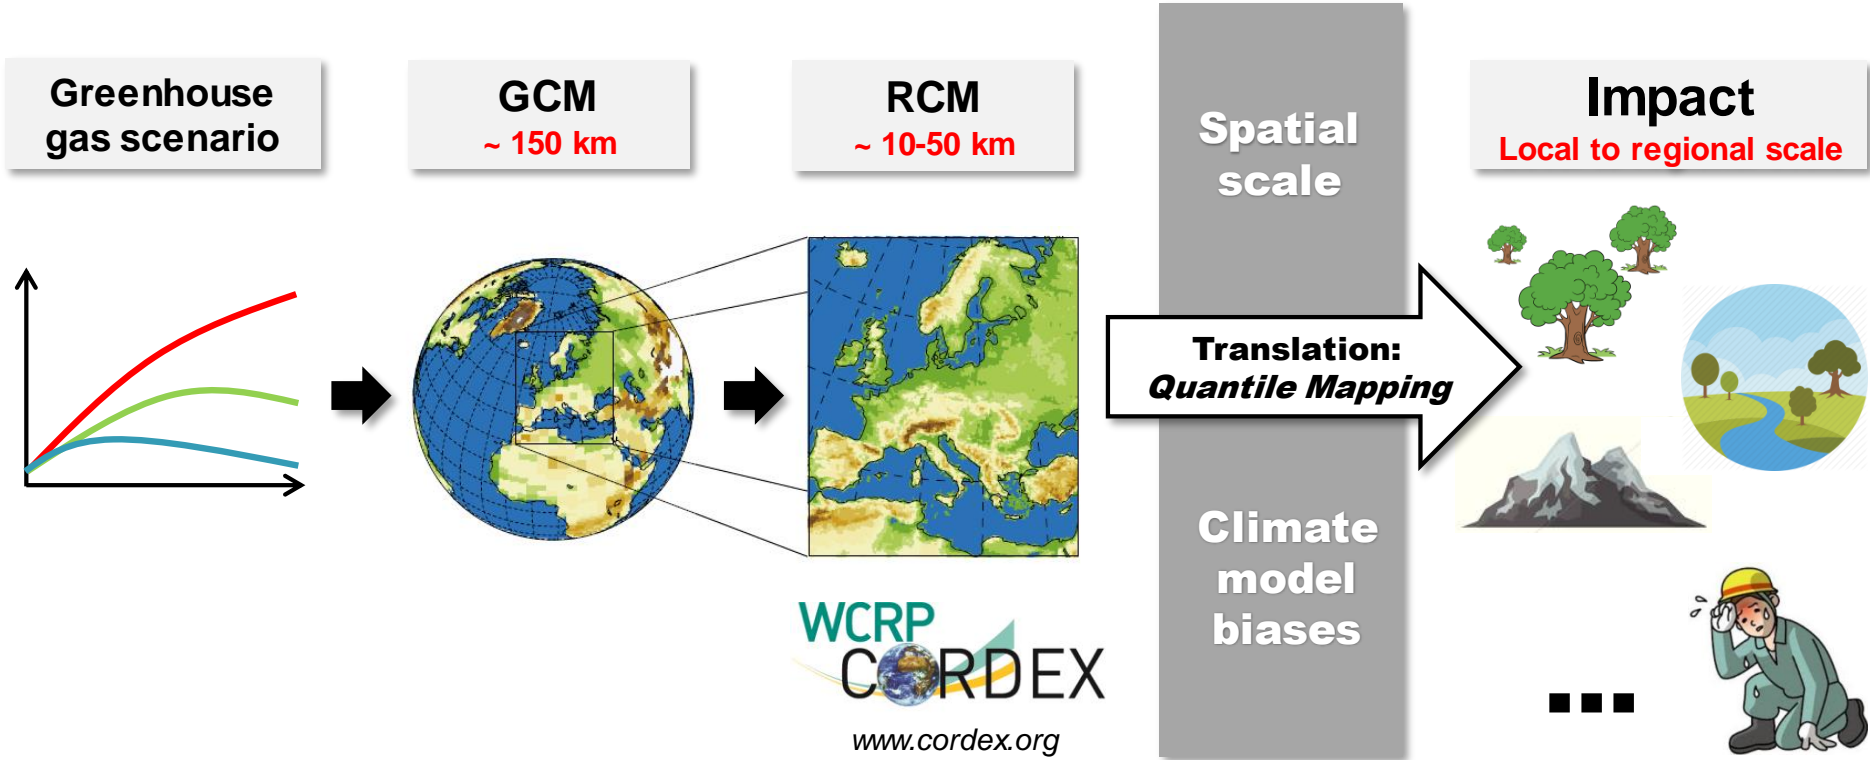

1981-2010

Reference: WFDEI (*Weedon et al. 2014*)
ERA-Interim corrected with NASA/GEWEX
Surface Radiation Budget data
(SRB; *Stackhouse Jr. et al., 2011*).
50km horiz. resolution.

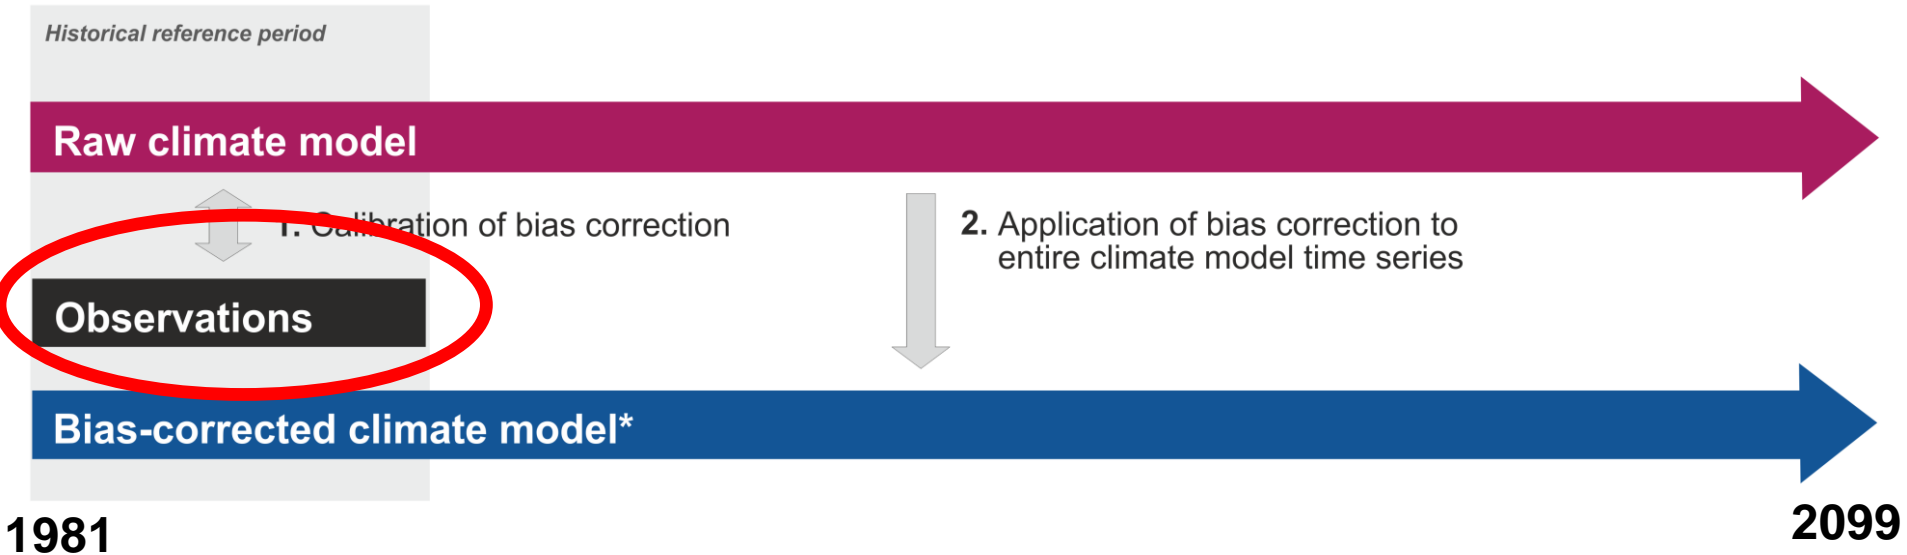

Climate projections: **The standard processing chain**

Bias adjustment by Quantile Mapping

Distribution-based adjustment of simulated data towards observations

*Reflects the spatial scale of the observations, i.e., can implicitly include a downscaling component

Challenge 1

Collect **daily** observations at a large number of European sites for **all required variables** and **for a climatological period (>30 years)**

Observational reference data

Temperature

*Dew point
temperature*

Wind

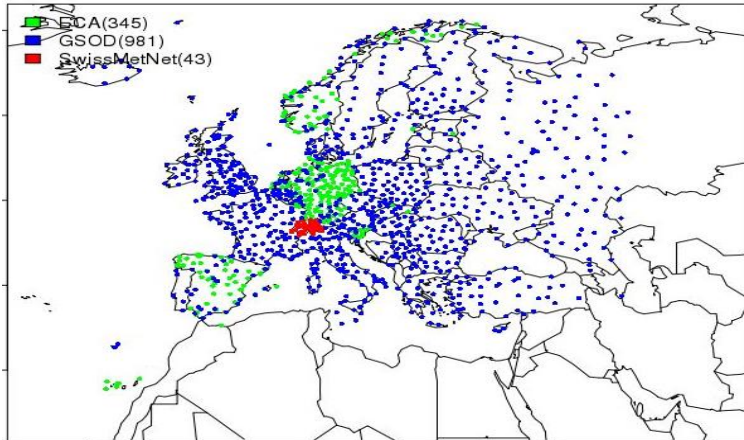

Solar radiation

Station data (1370 European stations)

Merge of three data sets

ECA, GSOD, SwissMetNet

SARAH satellite data

- Daily global radiation since 1983
 - 0.05° grid (5 km)
 - Closest grid to station

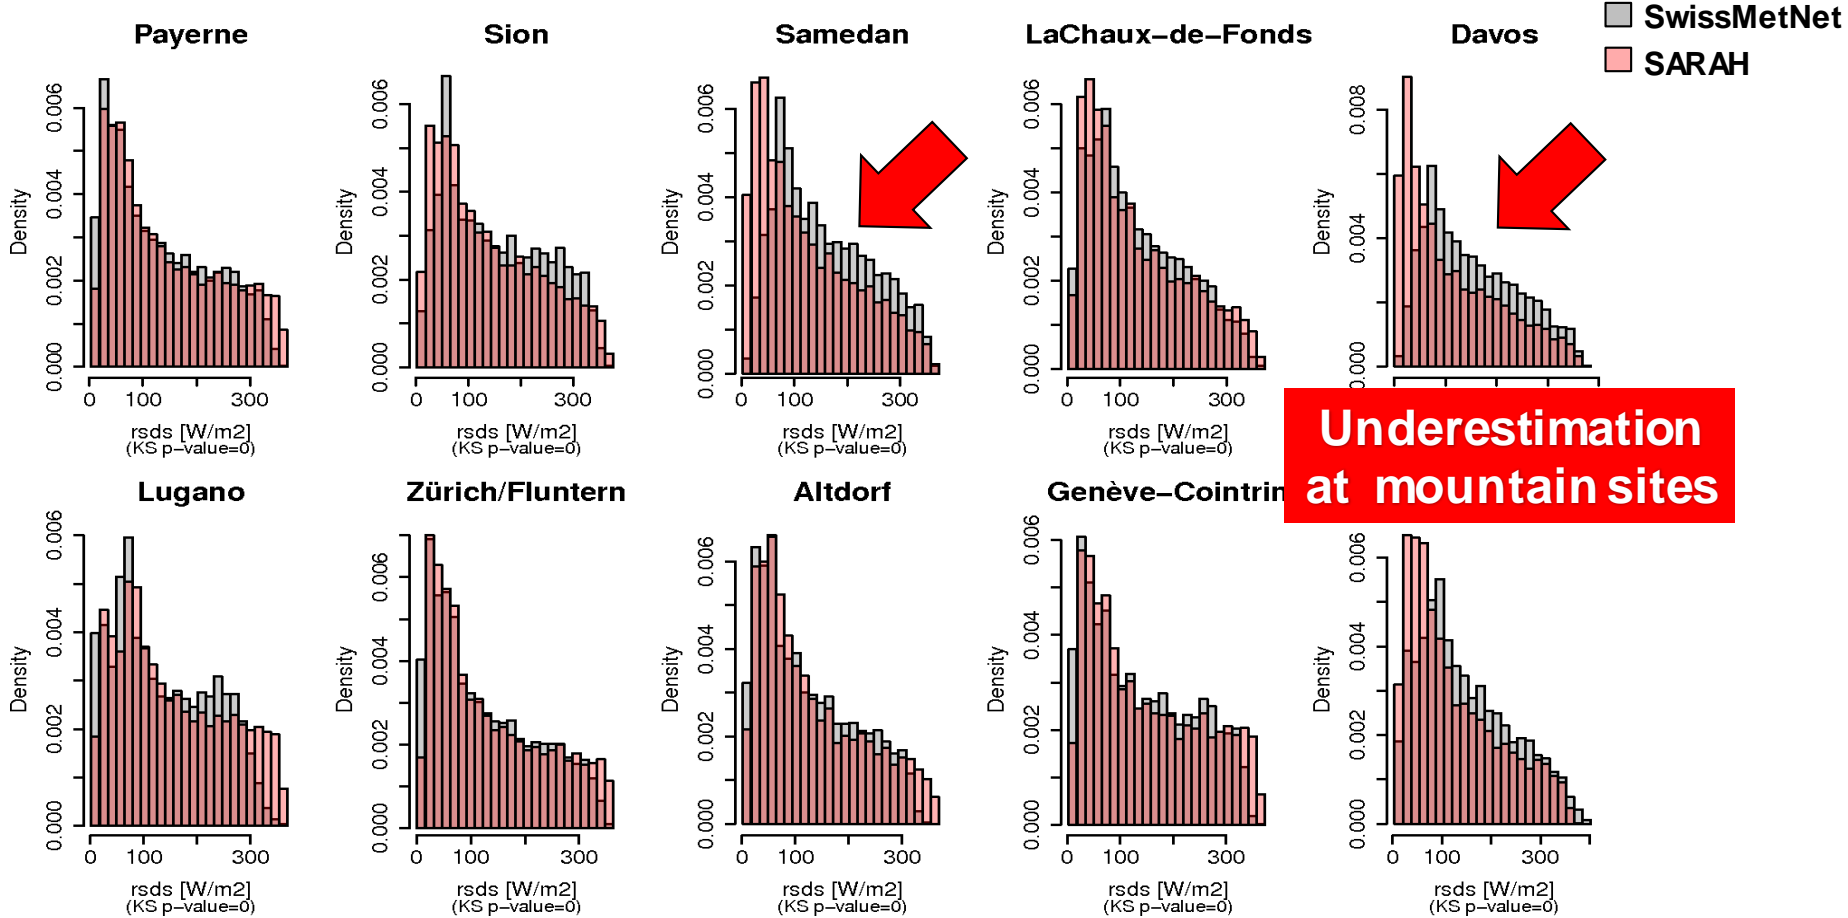

Challenge 2

Does it make sense to combine data from **stations** (temperature, dew point, wind) with **gridded** solar radiation?

**Validation of the approach
for Swiss stations
(global radiation available)**

SwissMetNet vs SARA H: solar radiation

SwissMetNet vs SARAH: **WBG**T

SwissMetNet
SARAH

Challenge 3

Station and gridded data provide **daily means** (and in some cases **daily max**)

Can we still derive
daily maximum heat stress?

Sensitivity analysis: Q-Q-plots of WGBT

Based on aggregated daily data

PAY

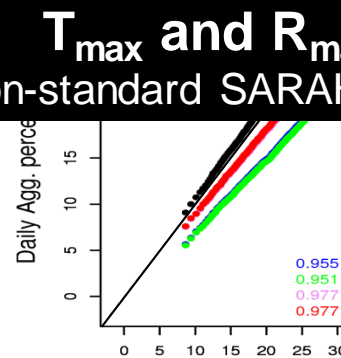

SIO

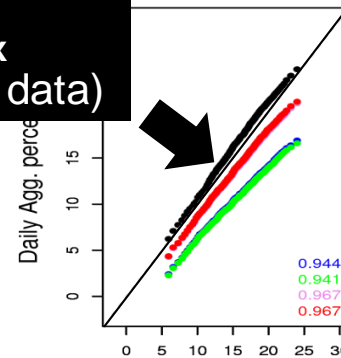

SAM

CDF

DAV

T_{max} and R_{max}
(non-standard SARAH data)

Based on hourly data

LUG

ALT

GVE

SAE

● WBGTto(T_{mean} , R_{mean} , 15h)

● WBGTto(T_{mean} , R_{mean} , 12h)

● WBGTto(T_{max} , R_{mean} , 12h)

● WBGTto(T_{max} , R_{mean} , 15h)

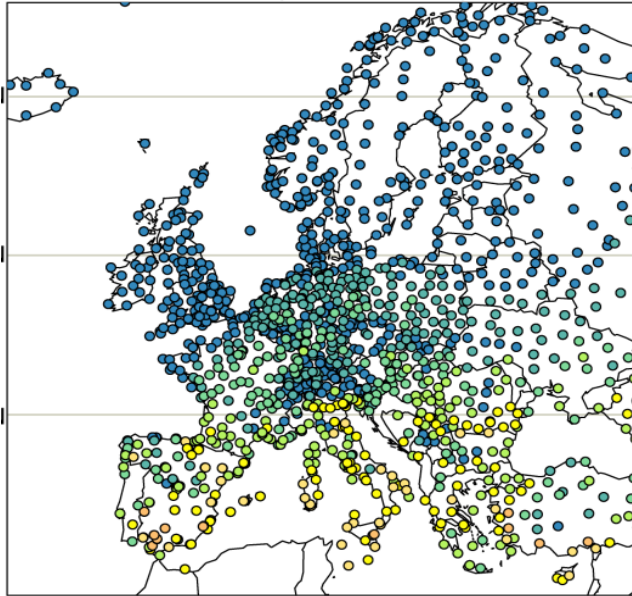

● WBGTto(T_{max} , R_{max} , 12h)

RESULTS

Summer maximum WBGT

Observations (1981-2010)

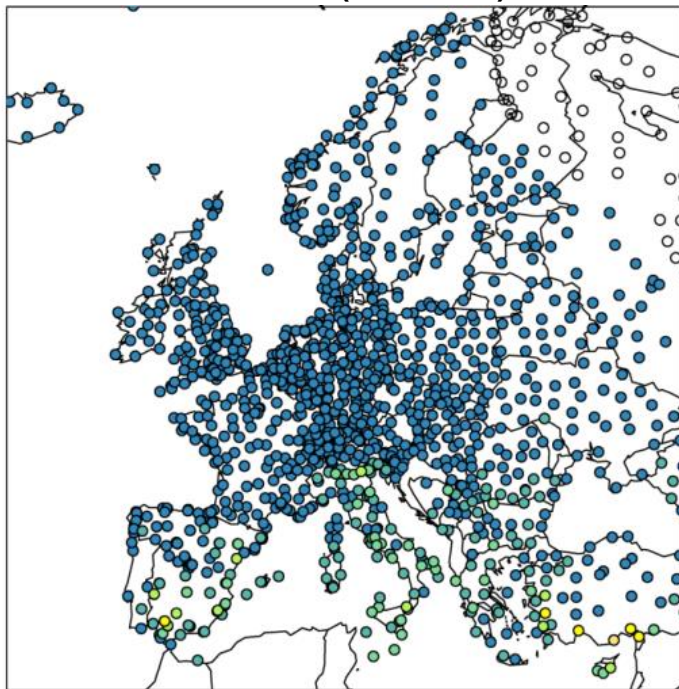

Summer maximum heat stress will increase by the end of the Century at all locations and will regularly reach critical levels in Southern Europe

Productivity losses due to heat stress

Observations (1981-2010)

**Major productivity losses,
especially in Southern Europe**

Conclusions

- **HEAT-SHIELD:** Reduction of heat stress and heat impacts on the European work force
- Long term **climate change projections of heat stress** on European scale

- Bias-adjustment of climate model data requires **high-quality reference**
- Solar radiation: Site measurements not available
- **SARAH product** turned out to be extremely valuable climatological series.

- **Expertise and help** of CM-SAF community (here: in-house) was essential
- Points to improve on

- Overview on and documentation of available datasets
- Quality of data in mountain regions
- High temporal resolution
